## **WEEK 1 QUIZ**

# **Recurrent Neural Networks**

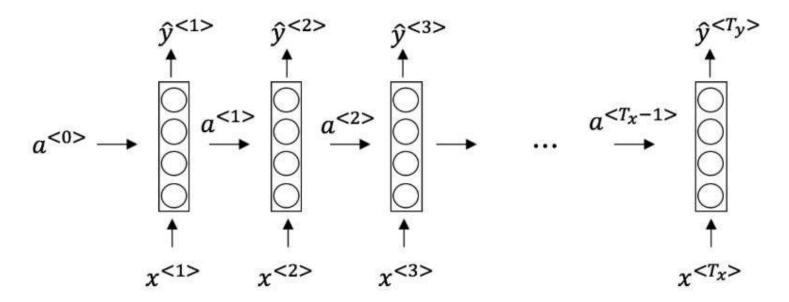

#### **TOTAL POINTS 10**

1. Suppose your training examples are sentences (sequences of words). Which of the following refers to the  $j^{th}$  word in the  $i^{th}$  training example?

- $\bigcap x^{< i > (j)}$
- $\bigcirc x^{(j) < i >}$
- $\bigcap x^{< j > (i)}$

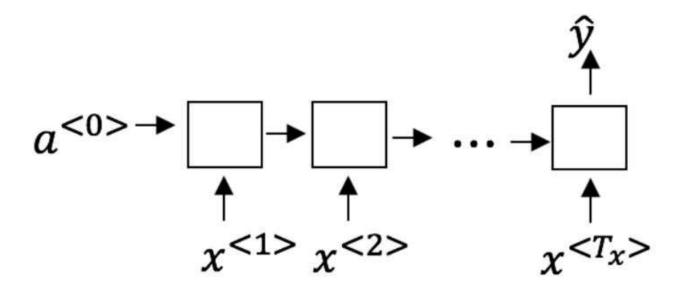

#### 2. Consider this RNN:

This specific type of architecture is appropriate when:

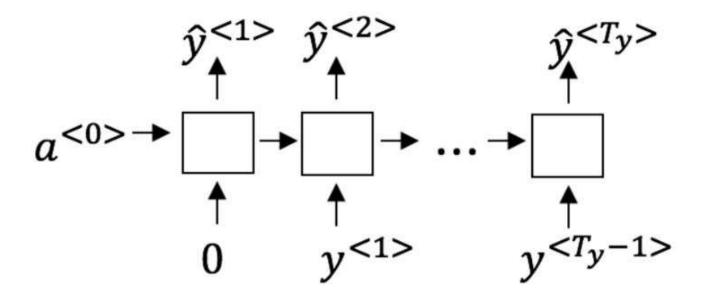

- $\bigcap T_x < T_y$
- $\bigcap T_x > T_y$
- $\bigcap T_x = 1$

3. To which of these tasks would you apply a many-to-one RNN architecture? (Check all that apply).

- Speech recognition (input an audio clip and output a transcript)
- Sentiment classification (input a piece of text and output a 0/1 to denote positive or negative sentiment)
- Image classification (input an image and output a label)
- Gender recognition from speech (input an audio clip and output a label indicating the speaker's gender)

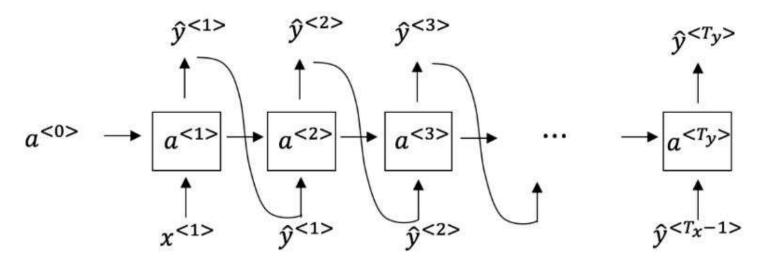

4. You are training this RNN language model.

At the  $t^{th}$  time step, what is the RNN doing? Choose the best answer.

- $\bigcirc \ \ \mathsf{Estimating} \ P(y^{<1>},y^{<2>},\dots,y^{< t-1>})$
- $\bigcirc$  Estimating  $P(y^{< t>})$
- igotimes Estimating  $P(y^{< t>} \mid y^{< 1>}, y^{< 2>}, \ldots, y^{< t-1>})$
- $\bigcirc$  Estimating  $P(y^{< t>} \mid y^{< 1>}, y^{< 2>}, \ldots, y^{< t>})$

5. You have finished training a language model RNN and are using it to sample random sentences, as follows:

What are you doing at each time step t?

- (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as  $\hat{y}^{< t>}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as  $\hat{y}^{< t>}$ . (ii) Then pass the ground-truth word from the training set to the next time-step.
- (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as  $\hat{y}^{< t>}$ . (ii) Then pass this selected word to the next time-step.
- (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as  $\hat{y}^{< t>}$ . (ii) Then pass this selected word to the next time-step.

6.	You are training an RNN, and find that your weights and activations are all taking on the value of NaN ("Not a Number"). Which of these is the most likely cause of this problem?
	O Vanishing gradient problem.
	Exploding gradient problem.
	ReLU activation function g(.) used to compute g(z), where z is too large.
	Sigmoid activation function g(.) used to compute g(z), where z is too large.
7.	Suppose you are training a LSTM. You have a 10000 word vocabulary, and are using an LSTM with 100-dimensional activations $a^{< t>}$ . What is the dimension of $\Gamma_u$ at each time step?
	O 1
	100
	O 300
	O 10000

8. Here're the update equations for the GRU.

#### GRU

$$\tilde{c}^{< t>} = \tanh(W_c[\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[c^{< t-1>}, x^{< t>}] + b_u)$$

$$\Gamma_r = \sigma(W_r[c^{< t-1>}, x^{< t>}] + b_r)$$

$$c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + (1 - \Gamma_u) * c^{< t-1>}$$

$$a^{< t>} = c^{< t>}$$

Alice proposes to simplify the GRU by always removing the  $\Gamma_u$ . I.e., setting  $\Gamma_u$  = 1. Betty proposes to simplify the GRU by removing the  $\Gamma_r$ . I. e., setting  $\Gamma_r$  = 1 always. Which of these models is more likely to work without vanishing gradient problems even when trained on very long input sequences?

- Alice's model (removing  $\Gamma_u$ ), because if  $\Gamma_r \approx 0$  for a timestep, the gradient can propagate back through that timestep without much decay.
- Alice's model (removing  $\Gamma_u$ ), because if  $\Gamma_r \approx 1$  for a timestep, the gradient can propagate back through that timestep without much decay.
- $igoreal{igoreal}$  Betty's model (removing  $\Gamma_r$ ), because if  $\Gamma_u \approx 0$  for a timestep, the gradient can propagate back through that timestep without much decay.
- O Betty's model (removing  $\Gamma_r$ ), because if  $\Gamma_u \approx 1$  for a timestep, the gradient can propagate back through that timestep without much decay.

9. Here are the equations for the GRU and the LSTM:

### GRU

$$\tilde{c}^{< t>} = \tanh(W_c[\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[c^{< t-1>}, x^{< t>}] + b_u)$$

$$\Gamma_r = \sigma(W_r[c^{< t-1>}, x^{< t>}] + b_r)$$

$$c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + (1 - \Gamma_u) * c^{< t-1>}$$

$$a^{< t>} = c^{< t>}$$

#### LSTM

$$\tilde{c}^{< t>} = \tanh(W_c[a^{< t-1>}, x^{< t>}] + b_c)$$

$$\Gamma_u = \sigma(W_u[a^{< t-1>}, x^{< t>}] + b_u)$$

$$\Gamma_f = \sigma(W_f[a^{< t-1>}, x^{< t>}] + b_f)$$

$$\Gamma_o = \sigma(W_o[a^{< t-1>}, x^{< t>}] + b_o)$$

$$c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + \Gamma_f * c^{< t-1>}$$

$$a^{< t>} = \Gamma_o * c^{< t>}$$

From these, we can see that the Update Gate and Forget Gate in the LSTM play a role similar to \_\_\_\_\_ and \_\_\_ in the GRU. What should go in the the blanks?

- $igotimes \Gamma_u$  and  $1-\Gamma_u$
- $\bigcap \Gamma_u$  and  $\Gamma_r$
- $\bigcap 1 \Gamma_u$  and  $\Gamma_u$
- $\bigcap \Gamma_r$  and  $\Gamma_u$

10.	You have a pet dog whose mood is heavily dependent on the current and past few days' weather. You've collected data for the past 365 days on the weather, which you represent as a sequence as $x^{<1>},\ldots,x^{<365>}$ . You've also collected data on your dog's mood, which you represent as $y^{<1>},\ldots,y^{<365>}$ . You'd like to build a model to map from $x\to y$ . Should you use a Unidirectional RNN or Bidirectional RNN for this problem?
	Bidirectional RNN, because this allows the prediction of mood on day t to take into account more information.
	Bidirectional RNN, because this allows backpropagation to compute more accurate gradients.
	O Unidirectional RNN, because the value of $y^{< t>}$ depends only on $x^{< 1>},\dots,x^{< t>}$ , but not on $x^{< t+1>},\dots,x^{< 365>}$
	O Unidirectional RNN, because the value of $y^{< t>}$ depends only on $x^{< t>}$ , and not other days' weather.
